effects of the combination of different types
of thymic stromal lymphopoietin inhibitors in

patients with multiple sclerosis. Thymic stromal lymphopoietin (TSLP) is a pro-inflammatory cytokine that contributes to the development and persistence of experimental autoimmune encephalomyelitis (EAE) in mice. TSLP is a target for novel drugs, including the monoclonal antibody Secukinumab, small molecule inhibitors (LY2439821 and BMS-986165) and humanised, afucosylated antibodies (ABP-501, ACZ885 and MEDI-563). In this study, we evaluate the safety and tolerability of the combination of different types of TSLP inhibitors in the treatment of patients with multiple sclerosis (MS). This is an open-label, exploratory study. Patients with active MS who completed a previous phase II study with an anti-TSLP monoclonal antibody a1d647c40b
